## LC BUTTERWORTH FILTERS

## arpenox E

Active filters (see Chapter 6) are convenient at low frequencies, but they are impractical at radio frequencies because of the slew-rate and bandwidth requirements they impose on the operational amplifiers. At frequencies of 100 kHz and above (and often at lower frequencies), the best approach is to design a passive filter with inductors and capacitors. (At UHF and microwave frequencies these "lumped-component" filters are replaced by stripline and cavity filters.)

As with active filters, there are many methods and filter characteristics possible with $L C$ filters. For example, you can design the classic Butterworth, Chebyshev, and Bessel filters, each in lowpass, bandpass, highpass, and band-reject varieties. It turns out that the Butterworth filter is particularly easy to design, and we can present in just a page or two all the essential design information for lowpass and highpass Butterworth $L C$ filters, and even a few examples.

## E. 1 Lowpass filter

Table E. 1 gives the values of normalized inductances and capacitances for low-pass filters of various orders, from which actual circuit values are obtained by the frequency and impedance scaling rules

$$
\begin{aligned}
L_{n}(\text { actual }) & =\frac{R_{\mathrm{L}} L_{n}(\text { table })}{\omega}, \\
C_{n}(\text { actual }) & =\frac{C_{n}(\text { table })}{\omega R_{\mathrm{L}}},
\end{aligned}
$$

where $R_{\mathrm{L}}$ is the load impedance and $\omega$ is the angular frequency ( $\omega=2 \pi f$ ).

Table E. 1 gives normalized values for two-pole through eight-pole lowpass filters for the two most common cases, namely (a) equal source and load impedances and (b) either source or load impedance much larger than the other. To use the table, first decide how many poles you need, based on the Butterworth response (graphs are plotted in Figure 6.30). Then use the preceding equations to determine the filter configuration ( $T$ or $\pi$; see Figure E.1) and component values. For equal source and load impedances, either

Figure E.1. $\pi$ and $T$ configurations. See Table E. 1 and text.
configuration is OK ; the $\pi$ configuration may be preferable because it requires fewer inductors. For a load impedance much higher (lower) than the source impedance, use the $T$ $(\pi)$ configuration.

## E. 2 Highpass filter

To design a highpass filter, follow the same procedure to determine which filter configuration to use and how many poles are necessary. Then do the universal lowpass to highpass transformation shown in Figure E.2, which consists simply of replacing inductors by capacitors, and vice versa. The actual component values are determined from the normalized values in Table E. 1 by the following frequency and impedance scaling rules:

$$
\begin{aligned}
L_{n}(\text { actual }) & =\frac{R_{\mathrm{L}}}{\omega C_{n}(\text { table })}, \\
C_{n}(\text { actual }) & =\frac{1}{R_{\mathrm{L}} \omega L_{n}(\text { table })} .
\end{aligned}
$$

## E. 3 Filter examples

Here are a few examples showing how to design both lowpass and highpass filters.

Example I. Design a five-pole lowpass filter for source

Table E. 1 Butterworth Lowpass Filters ${ }^{\text {a }}$

Notes: (a) Values of $L_{n}, C_{n}$ for $1 \Omega$ load resistance, and cutoff frequency $(-3 \mathrm{~dB})$ of $1 \mathrm{rad} / \mathrm{s}$. See text for scaling rules.
and load impedances of $75 \Omega$, with a cutoff frequency $(-3 \mathrm{~dB})$ of 1 MHz .

We use the $\pi$ configuration to minimize the number of required inductors. The scaling rules give us

$$
\begin{gathered}
C_{1}=C_{5}=\frac{0.618}{2 \pi \times 10^{6} \times 75}=1310 \mathrm{pF} \\
L_{2}=L_{4}=\frac{75 \times 1.618}{2 \pi \times 10^{6}}=19.3 \mu \mathrm{H} \\
C_{3}=\frac{2}{2 \pi \times 10^{6} \times 75}=4240 \mathrm{pF}
\end{gathered}
$$

The complete filter is shown in Figure E.3. Note that all filters with equal source and load impedances will be symmetrical.

Figure E.2. Lowpass to highpass transformation.

Example II. Design a three-pole lowpass filter for a

Figure E.3. Circuit for Example I. Five-pole 1 MHz lowpass with equal source and load impedances.
source impedance of $50 \Omega$ and a load impedance of 10 k , with a cutoff frequency of 100 kHz .

We use the $T$ configuration, because $R_{\mathrm{S}} \ll R_{\mathrm{L}}$. For $R_{\mathrm{L}}=10 \mathrm{k}$, the scaling rules give

$$
\begin{gathered}
L_{1}=\frac{10^{4} \times 1.5}{2 \pi \times 10^{5}}=23.9 \mathrm{mH} \\
C_{2}=\frac{1.3333}{2 \pi \times 10^{5} \times 10^{4}}=212 \mathrm{pF} \\
L_{3}=\frac{10^{4} \times 0.5}{2 \pi \times 10^{5}}=7.96 \mathrm{mH}
\end{gathered}
$$

The complete filter is shown in Figure E.4.
Example III. Design a four-pole lowpass filter for a zeroimpedance source (voltage source) and a $75 \Omega$ load, with a cutoff frequency of 10 MHz .

We use the $T$ configuration, as in the previous example,

Figure E.4. Circuit for Example II. Three-pole 100 kHz lowpass with $50 \Omega$ source and 10 k load.
because $R_{\mathrm{S}} \ll R_{\mathrm{L}}$. The scaling rules give

$$
\begin{aligned}
& L_{1}=\frac{75 \times 1.5307}{2 \pi \times 10^{7}}=1.83 \mu \mathrm{H} \\
& C_{2}=\frac{1.5772}{2 \pi \times 10^{7} \times 75}=335 \mathrm{pF} \\
& L_{3}=\frac{75 \times 1.0824}{2 \pi \times 10^{7}}=1.29 \mu \mathrm{H} \\
& C_{4}=\frac{0.3827}{2 \pi \times 10^{7} \times 75}=81.2 \mathrm{pF}
\end{aligned}
$$

The complete filter is shown in Figure E.5.

Figure E.5. Circuit for Example III. Four-pole 10 MHz lowpass with voltage source and $75 \Omega$ load.

Example $\mathbb{V}$. Design a two-pole lowpass filter for currentsource drive and 1 k load impedance, with a cutoff frequency of 10 kHz .

We use the $\pi$ configuration because $R_{\mathrm{S}} \gg R_{\mathrm{L}}$. The scaling rules give

$$
\begin{gathered}
C_{1}=\frac{1.4142}{2 \pi \times 10^{4} \times 10^{3}}=0.0225 \mu \mathrm{~F} \\
L_{2}=\frac{10^{3} \times 0.7071}{2 \pi \times 10^{4}}=11.3 \mathrm{mH}
\end{gathered}
$$

The complete filter is shown in Figure E.6.

Figure E.6. Circuit for Example IV. Two-pole 10 MHz lowpass with current source drive and 1 k load.

Example V. Design a three-pole highpass filter for $52 \Omega$ source and load impedances, with a cutoff frequency of 6 MHz .

We begin with the $T$ configuration, then transform inductors to capacitors, and vice versa, giving

$$
\begin{gathered}
C_{1}=C_{3}=\frac{1}{52 \times 2 \pi \times 6 \times 10^{6} \times 1.0}=510 \mathrm{pF}, \\
L_{2}=\frac{52}{2 \pi \times 6 \times 10^{6} \times 2.0}=0.690 \mu \mathrm{H} .
\end{gathered}
$$

The complete filter is shown in Figure E.7.

Figure E.7. Circuit for Example V. Three-pole 6 MHz highpass with equal source and load impedances.

We would like to emphasize that the field of passive filter design is rich and varied and that this simple table of Butterworth filters doesn't even begin to scratch the surface.
